

AR Match Pro — Security & Privacy Data Sheet

For IT and security reviewers · July 2026 · armatchpro.com · info@armatchpro.com

The one-sentence answer

Your financial data is processed entirely inside your browser tab and is never transmitted to AR Match Pro servers — there are no AR Match Pro servers in the data path. Matching, OCR, parsing, and export generation all execute locally on your machine.

Architecture

AR Match Pro is a client-side web application. When your team uploads bank statements, open-invoice reports, remittance advices, or delivery reports, the files are read by JavaScript running in the browser tab. The matching engine, the OCR engine (Tesseract compiled to WebAssembly), and the PDF reader all run locally. Posting exports (SAP F-28, NetSuite Cash Receipt, Dynamics 365 F&O, CSV, Excel) are generated in the browser and saved directly to your machine.

Question	Answer
Where is our bank data processed?	In your browser tab, on your machine. Never uploaded.
Where is it stored?	Browser local storage on your machine only, scoped per user, so a session survives a refresh. Datasets above the browser storage quota run in-memory only (the app tells you, and you export before closing). Clearing browser data removes everything.
What does the network see during matching?	Nothing. Zero outbound requests are made during import, matching, review, or export. This is asserted by an automated test on every build: any fetch, XMLHttpRequest, beacon, or WebSocket call during those flows fails the release.
What DOES load from the internet?	Static application code and libraries only (spreadsheet reader, OCR engine, PDF reader) from pinned public CDNs, plus the OCR language model. These are inbound code downloads — no customer data travels in either direction. A Content-Security-Policy header pins the exact allowed origins and blocks everything else.
Analytics / telemetry?	None. No usage beacons, no session recording, no third-party analytics scripts.
Payment card data?	Subscription billing is handled by Stripe on Stripe's own hosted components. AR Match Pro never sees card numbers. Billing is unrelated to your financial data files.

The one optional feature that transmits data — clearly marked

AR Match Pro includes an **optional** AI-assisted remittance parser for unusually formatted remittance documents. It is off by default, requires the user to paste their **own** Anthropic API key, and only runs when the user explicitly clicks it — at which point the content of that one remittance document is sent to the Anthropic API for extraction. No bank statements, invoice books, or credentials are ever included. Organizations that prohibit this can simply not configure a key; every core workflow functions without it.

Verify it yourself in two minutes

1. Open AR Match Pro and press F12 → Network tab. 2. Clear the log after the page loads. 3. Import your files and click Run Auto Match. 4. Observe: zero requests during import and matching. This is the fastest security review you will do this year — we designed for it.

Auditability

Every import, rejected file, Auto Match run, manual override, exception resolution, and export is written to a timestamped in-app audit trail identifying the actor (user or matching rule). Exported records are locked to preserve the trail. Match confidence scores are itemized sums of objective signals, so any allocation can be explained to an external auditor line by line.

Compliance roadmap

Because customer financial data never reaches AR Match Pro infrastructure, the platform's attack surface for your data is your own endpoint and browser — which your existing endpoint controls already govern. AR Match Pro is preparing for SOC 2 Type II examination covering its application delivery and corporate controls; status available on request.
